ABSTRACT: Via the AdS/CFT correspondence, ground states of field theories at finite charge density are mapped to extremal black brane solutions. Studies of simple gravity + matter systems in this context have uncovered wide new classes of extremal geometries. The Lifshitz metrics characterising field theories with non-trivial dynamical critical exponent $z \neq 1$ emerge as one common endpoint in doped holographic toy models. However, the Lifshitz horizon exhibits mildly singular behaviour - while curvature invariants are finite, there are diverging tidal forces. Here we show that in some of the simplest contexts where Lifshitz metrics emerge, Einstein-Maxwell-dilaton theories, toy models of generic corrections can lead (presumably as one possibility among many) to a replacement of the Lifshitz metric, in the deep infrared, by a re-emergent $AdS_2 \times R^2$ geometry. Thus, at least in these cases, the Lifshitz scaling characterises the physics over a wide range of energy scales, but the mild singularity is cured by quantum or stringy effects.

1 Introduction

There has been significant recent interest in applying the techniques of gauge/gravity duality to learn about the phase structure of holographic toy models of condensed matter physics (for reviews, see [1–4]). The gravitational theory “geometrizes” many questions of physical interest, such as the behaviour of quantum field theory at a finite temperature or charge density. In particular, ground states of field theory at finite charge density are mapped to extremal black brane geometries, and the classification of the latter can provide a holographic window into possible novel phases of doped matter.

Several new types of horizons have emerged in this holographic study of doped field theories (with a coarse attempt at the classification of such horizons, in the homogeneous case, appearing recently in [5]). One of the simplest features of critical points in condensed matter physics that would distinguish them from the theories usually studied by particle/string theorists is the presence of “dynamical scaling.” This is a scale invariance under which

$$t \rightarrow \lambda^z t, \quad x_i \rightarrow \lambda x_i \quad (1.1)$$

with $z \neq 1$. While the $z \neq 1$ theories are not Lorentz invariant, they emerge rather naturally as fixed points in many condensed matter models, where Lorentz symmetry is broken.

The geometries dual to such field theories were described in [6], where they were found as solutions of simple 4d gravity theories with reasonable matter content. String theory and supergravity embeddings have been found in [7–13]. The dual metric takes the form

$$ds^2 = -r^{2z} dt^2 + r^2 dx_i^2 + \frac{dr^2}{r^2} . \quad (1.2)$$

This metric has constant curvature, but the “Lifshitz horizon” at $r=0$ has diverging tidal forces, as discussed in [6, 14, 15]. While a tiny temperature can regulate these forces, and in many similar cases such singularities are known to be harmless and physically

admissible [16], it is an open question in this case what the correct interpretation of the singularities is.¹ The results of this note will *not* apply to the solutions, like those of [6], which have exact Lifshitz scaling symmetry.

More generally, these metrics also emerge naturally in relativistic systems which are doped by finite charge density. For instance, asymptotically AdS extremal black branes whose near-horizon geometry is of the Lifshitz form were found in [17, 18] by studying the solutions of the theory with action

$$S = \int d^4x \sqrt{-g} \left(R - 2(\nabla\phi)^2 - e^{2\alpha\phi} F^2 - 2\Lambda \right). \quad (1.3)$$

In these theories, although the metric in the IR takes the Lifshitz form with $z = \frac{1+(\frac{\alpha}{2})^2}{(\frac{\alpha}{2})^2}$, the scalar dilaton is logarithmically running. Both electrically and magnetically charged black branes give rise to such geometries: in the former the dilaton runs towards weak coupling at the horizon (in the sense that $g \equiv e^{-\alpha\phi} \rightarrow 0$), while in the latter, the dilaton runs towards strong coupling. Related solutions with Lifshitz asymptotics were first discussed in [19], and several other papers exploring closely related solutions have subsequently appeared [20–32].

It was noted already in [17, 18] that the running of the dilaton means that one cannot trust the Lifshitz form of the solutions to the action (1.3) in the very deep IR. In the case of the magnetically charged branes, this is because as g grows, quantum corrections should be expected to grow in importance — see section 4.2 of [18]. For electrically charged branes, on the other hand, it would be expected that in string theory α' corrections (i.e., higher-derivative terms) would become important.

We have already seen cases in string theory where α' corrections “resolve” a horizon which is naively singular [33]. Here, we discuss an analogous phenomenon for black branes. Instead of α' corrections we will focus on the quantum corrections to the near-horizon geometry of the magnetically charged black branes in quantum-corrected versions of the theory (1.3). As a simplest toy model for these corrections in g , we will promote the gauge kinetic term in (1.3)

$$e^{2\alpha\phi} F^2 \rightarrow f(\phi) F^2 \quad (1.4)$$

with the “gauge coupling function” $f(\phi)$ taking the form

$$f(\phi) = e^{2\alpha\phi} + \xi_1 + \xi_2 e^{-2\alpha\phi} + \xi_3 e^{-4\alpha\phi} + \dots = \frac{1}{g^2} + \xi_1 + \xi_2 g^2 + \xi_3 g^4 + \dots \quad (1.5)$$

The new terms $\sim \xi_i$ in the gauge coupling function are meant to mock up the quantum corrections which become important as the coupling constant grows near the horizon. We will mostly truncate to the case where only $\xi_{1,2}$ appear. This is largely to make a particularly tractable toy model, and we suspect (for reasons we describe in the discussion, after analyzing the toy model) this is not qualitatively important for our results. We shall see that for this form of f (and for more generic forms that include further terms, as long

¹It is rather natural to think that because theories with dispersion relation $\omega = k^z$ for $z > 1$ have more “soft modes” than conventional relativistic theories, the tidal forces are a dual avatar of the more complicated structure of IR singularities in such theories.

as a suitable condition is satisfied), the geometry of the magnetic black brane is changed in the very near-horizon limit.²

For the asymptotically AdS brane, the resulting structure is as follows. The UV fixed point is a Lorentz-invariant CFT perturbed by a magnetic field (corresponding to the magnetically charged brane). Along the renormalisation group trajectory, one flows very close to a Lifshitz fixed point with $z = \frac{1+(\frac{\alpha}{2})^2}{(\frac{\alpha}{2})^2}$, and hovers in the vicinity of the fixed point for decades in energy scale. (By tuning parameters, one can increase the number of decades of energy over which the theory is controlled by this fixed point). Finally, in the deep IR, the coupling g grows appreciable enough that the corrections in (1.5) become important. The result is an emergent $AdS_2 \times R^2$ geometry, which smoothly ends the flow and resolves the Lifshitz horizon which was present in the “uncorrected” theory. We discuss the analytical form of the deep IR $AdS_2 \times R^2$ solution in section 2, and we present numerical solutions showing the three scaling regions in appropriate RG flows in section 3. We conclude with a discussion in section 4.

2 $AdS_2 \times R^2$ solutions of the quantum corrected action

We consider an Einstein-Maxwell-dilaton theory including simple loop corrections to the gauge coupling function. The full action is:

$$S = \int d^4x \sqrt{-g} (R - 2(\nabla\phi)^2 - f(\phi)F^2 - 2\Lambda), \quad (2.1)$$

with $f(\phi)$ given by equation (1.5) and only $\xi_{1,2} \neq 0$. The Einstein equations coming from this action take the form

$$R_{\mu\nu} + (\Lambda - \frac{1}{2}R)g_{\mu\nu} = T_{\mu\nu} \quad (2.2)$$

where we have set $8\pi G_N = 1$. The stress-energy tensor is:

$$T_{\mu\nu} = 2f(\phi) \left(F_{\mu\rho}F_{\nu}^{\rho} - \frac{g_{\mu\nu}}{4}F^{\rho\sigma}F_{\rho\sigma} \right) + 2 \left(\partial_{\mu}\phi\partial_{\nu}\phi - \frac{g_{\mu\nu}}{2}\partial^{\rho}\phi\partial_{\rho}\phi \right) \quad (2.3)$$

When $\xi_1 = \xi_2 = 0$, the action reduces to that of equation (1.3), and the theory has charged black holes with a near-horizon Lifshitz-like metric, as well as a logarithmically running dilaton [17, 19]. Here, we exhibit exact $AdS_2 \times R^2$ magnetically-charged solutions of the theory after including the corrections to the gauge-coupling function. As in [17], we then modify the exact near-horizon solution to glue the system into an asymptotically AdS_4 geometry. We will see that, unsurprisingly, one can easily arrange to (approximately) match on to the Lifshitz-like solutions seen in the earlier works for large intermediate regions of our holographic RG flows.

²It is reasonable to wonder what would happen on inclusion of a ϕ potential in (1.3). Such solutions have also been explored, e.g. in [22]. Inclusion of potentials of the sort studied in [22] would not change our conclusions qualitatively, though they do lead to a more general class of metrics (involving also a hyperscaling exponent) along the RG flow; we comment in more detail on this point in section 4.

Now, we demonstrate that this theory admits $AdS_2 \times R^2$ solutions.³ To begin with, assume that the effective attractor potential for the dilaton stabilizes it at some value ϕ_H . The metric is given by

$$ds^2 = L^2 \left(-r^2 dt^2 + \frac{dr^2}{r^2} + b^2(dx^2 + dy^2) \right), \quad (2.4)$$

and the background gauge field strength by

$$F = Q_m dx \wedge dy. \quad (2.5)$$

Note that b and Q_m can be changed by re-scaling the field theory spatial coordinates; we set our conventions at the end of this section.

It is convenient to think of the metric $g_{\mu\nu}$ in terms of two sub-blocks, $g_{\alpha\beta}$ with α, β running over x, y and g_{ab} with a, b running over r, t . Then with $\phi = \phi_H$ and the metric and gauge fields as above, we see that

$$T_{\alpha\beta} = \frac{1}{4} \frac{Q_m^2}{L^4 b^4} f(\phi_H) g_{\alpha\beta}, \quad T_{ab} = -\frac{1}{4} \frac{Q_m^2}{L^4 b^4} f(\phi_H) g_{ab}. \quad (2.6)$$

The xx and yy Einstein equations yield

$$\Lambda - \frac{1}{2}R = \frac{1}{4} \frac{Q_m^2}{L^4 b^4} f(\phi_H) \quad (2.7)$$

while the rr and tt Einstein equations become:

$$\frac{1}{L^2} - \left(\Lambda - \frac{1}{2}R \right) = \frac{1}{4} \frac{Q_m^2}{L^4 b^4} f(\phi_H). \quad (2.8)$$

Here, R is the scalar curvature $-\frac{2}{L^2}$ of $AdS_2 \times R^2$.

The value of ϕ_H can be found from the equation of motion for ϕ ,

$$-\frac{4}{b^2 L^2} \partial_r (b^2 \partial_r \phi) = \partial_\phi (-f(\phi) F^2) \quad (2.9)$$

$$= \frac{\alpha Q_m^2}{b^4 L^4} (\xi_2 e^{2\alpha\phi} - e^{-2\alpha\phi}), \quad (2.10)$$

assuming ϕ constant. The solution we find for the effective coupling $g = e^{-\alpha\phi}$, is simply

$$e^{-\alpha\phi_H} = \xi_2^{-1/4}. \quad (2.11)$$

So we see that in the reasonably generic parameter range $\xi_2 > 0$, quantum corrections to the gauge-coupling function can produce an attractor potential which yields a non-trivial minimum for the dilaton. This minimum is at weak coupling for large ξ_2 and strong coupling for ξ_2 small. We discuss the robustness of these results (under incorporation of e.g. further corrections) in section 4.

³After completing this work, we were informed that closely related magnetic $AdS_2 \times R^2$ solutions were also found in rather general Einstein-Maxwell-dilaton systems in section 5 of [34].

Plugging ϕ_H back into the r.h.s. of the Einstein equations, (2.7) and (2.8), we obtain for, e.g., (2.7):

$$\Lambda - \frac{1}{2}R = \frac{Q_m^2}{4L^4b^4}(2\sqrt{\xi_2} + \xi_1). \quad (2.12)$$

The Einstein equations can then be solved for the two remaining degrees of freedom, Q_m and L^2 , in terms of Λ , which gives us

$$\frac{1}{L^2} = -2\Lambda, \quad Q_m^2 = \frac{2L^2b^4}{2\sqrt{\xi_2} + \xi_1}. \quad (2.13)$$

This solution is sensible in the parameter range $\Lambda < 0$, $\xi_2 > 0$, and $\xi_1 > -2\sqrt{\xi_2}$.

Here we have kept b as a parameter, and determined Q_m as a function of b . In fact in the AdS_2 solution we can choose a gauge where $Q_m \equiv 2$. We shall use this to fix our initial value of b when we “shoot” to AdS_4 asymptotics in the next section. The full AdS_4 flows are then really characterised by two parameters: ϕ_∞ and Q_m . While this may seem to be in tension with the fact that Q_m is fixed in the near-horizon region by (2.13), the tension is illusory. Q_m sets the only scale in the UV theory, and theories with different values are related by coordinate re-scalings, as in [17].

3 RG flows

Here, we find full solutions with $AdS_2 \times R^2$ in the deep IR, a large Lifshitz scaling region along the flow to the UV, and asymptotically AdS_4 boundary conditions. We do this as follows. First, we find linearized solutions to the equations for fluctuations around $AdS_2 \times R^2$, which vanish faster than the leading order background fields as $r \rightarrow 0$ - these are irrelevant perturbations of the IR fixed point. We then add them with appropriate coefficients to generate a flow as one goes to larger values of r , and solve the equations using standard “shooting” techniques to hit AdS_4 . We will find that quite naturally, large Lifshitz scaling regions (matching onto the solutions of [17, 18]) appear along the flow. We begin by sketching the qualitative nature of the expected flow analytically.

3.1 Intuitive picture of flow

Here, we describe how we can design solutions which match those of [17, 18] over a wide range of scales. Suppose we begin with a weak coupling $g = e^{-\phi_\infty}$ at the AdS_4 boundary. We choose the asymptotic coupling so that $f(\phi)$ is dominated by the classical term,

$$\frac{1}{g^2} \gg (\xi_1 + \xi_2 g^2). \quad (3.1)$$

Then starting close to the boundary, we will match the (magnetic version of) the solutions flowing from AdS_4 to Lifshitz, studied in [17, 18].

The theory will depart from AdS_4 scaling and approach the Lifshitz form when the contribution from $e^{-2\alpha\phi}F^2$ in the action is comparable to the contribution from the cosmological term. This happens when $g^{xx}g^{yy}F_{xy}^2 \sim \frac{g^2}{L^2}$, so given that the dilaton is approximately

constant in the AdS_4 region, the crossover to the Lifshitz scaling happens when

$$r^4 \sim \frac{Q_m^2 L^2}{b_\infty^4 e^{-2\alpha\phi_\infty}} . \quad (3.2)$$

Here, the parameter b_∞ is the coefficient of the linear term in the function $b(r)$ in (3.5) at infinity, $b(r) \sim b_\infty r$. We are not free to re-scale this to one because we have chosen to shoot starting from the value of b , b_H , that yields $Q_m(b_H) = 2$ in the $AdS_2 \times R^2$ region.

In the magnetically charged brane solution of (1.3) (section 4 of [18]), once one is in the near-horizon region, the dilaton grows as

$$g = e^{-\alpha\phi} \sim \left(\frac{1}{r}\right)^{\alpha K}, \quad K \equiv \frac{\frac{\alpha}{2}}{1 + (\frac{\alpha}{2})^2} . \quad (3.3)$$

For any fixed ξ_1 and ξ_2 in the range of parameters discussed in section 2, we will then eventually violate the condition (3.1) as g grows, as soon as

$$\xi_2 g^4 + \xi_1 g^2 \simeq 1 . \quad (3.4)$$

If $\xi_1^2 > \xi_2$, this crossover occurs before one hits the attractor value of the dilaton (2.11).

Since one is free to tune ϕ_∞ at the AdS_4 UV fixed point, for an open set of sufficiently weak couplings, the crossover from AdS_4 to Lifshitz occurs well before the crossover from Lifshitz scaling to the AdS_2 attractor. As one makes g_∞ weaker, then, the number of decades of the renormalisation group flow controlled by the approximate Lifshitz fixed point grows.

3.2 Corrections to the near horizon solution

Now we consider the general metric,

$$ds^2 = L^2(-a(r)^2 dt^2 + \frac{1}{a(r)^2} dr^2 + b(r)^2(dx^2 + dy^2)) \quad (3.5)$$

and allow for $\phi = \phi(r)$. The Ricci tensor and scalar curvature are now more complicated functions of r . The scalar curvature is

$$R = \frac{2(b^2 a'^2 + 4aba'b' + a^2 b'^2 + ab^2 a'' + 2a^2 b b'')}{L^2 b^2} . \quad (3.6)$$

The components of the Einstein equations, $R_{\mu\nu} + (\Lambda - \frac{1}{2}R)g_{\mu\nu} = T_{\mu\nu}$, are now

$$\text{LHS}_{tt} = \frac{a^2}{2b^2}(b^2 - 2a^2 b'^2 - 4ab(a'b' + ab'')) \quad (3.7)$$

$$\text{LHS}_{rr} = -\frac{1}{2a^2} + \frac{2a'b'}{ab} + \frac{b'}{b^2} \quad (3.8)$$

$$\text{LHS}_{ab} = \frac{1}{2}b(b(2a'^2 + 2aa'' - 1) + 2a(2a'b' + ab'')) \quad (3.9)$$

for the left hand side, and

$$T_{tt} = \frac{1}{4} \frac{Q_m^2}{L^2} \frac{a^2}{b^4} f(\phi) + a^4 \phi'^2 \quad (3.10)$$

$$T_{rr} = -\frac{1}{4} \frac{Q_m^2}{L^2} \frac{1}{a^2 b^4} f(\phi) + \phi'^2 \quad (3.11)$$

$$T_{ab} = \frac{1}{4} \frac{Q_m^2}{L^2} \frac{1}{b^2} f(\phi) - a^2 b^2 \phi'^2 \quad (3.12)$$

for the stress-energy tensor.

We perturb around the $AdS_2 \times R^2$ solution:

$$a(r) = r(1 + d_1 r^\nu), \quad b(r) = b_H(1 + d_2 r^\nu), \quad \phi(r) = \phi_H(1 + d_3 r^\nu), \quad (3.13)$$

and keep the lowest order terms in d_1 , d_2 , and d_3 . The Einstein equations at lowest order are

$$(\nu^2 - 1)d_2 = 0 \quad (3.14)$$

$$(\nu - 1)d_2 = 0 \quad (3.15)$$

$$(\nu + 1)(\nu + 2)d_1 + (\nu^2 + \nu + 2)d_2 = 0 \quad (3.16)$$

for t , r , and x, y respectively. We get an additional constraint from expanding equation (2.9), the equation of motion for ϕ ,

$$\left[\frac{2\alpha^2 \sqrt{\xi_2}}{2\sqrt{\xi_2} + \xi_1} - \nu(\nu + 1) \right] d_3 = 0. \quad (3.17)$$

Because we require that $\nu > 0$ so that the perturbations die away at small r , we have two modes which are irrelevant at small r :

$$\nu = 1, \quad d_2 = -\frac{3}{2}d_1, \quad d_3 = 0 \quad (3.18)$$

and

$$\nu = \frac{1}{2} \left[\sqrt{1 + \frac{8\alpha^2 \sqrt{\xi_2}}{\xi_1 + 2\sqrt{\xi_2}}} - 1 \right], \quad d_1, d_2 = 0. \quad (3.19)$$

These are the modes that will control the RG evolution of the $AdS_2 \times R^2$ solution as $r \rightarrow \infty$.

3.3 Flows to Lifshitz and AdS_4

In this section we show plots evincing the evolution of the near-horizon $AdS_2 \times R^2$ solution as it approaches the UV. As predicted in section 3.1, the solution always asymptotically reaches AdS_4 , independent of the coefficients of the irrelevant modes, while hitting an intermediate Lifshitz regime over a range of energies, which can be tuned to be arbitrarily large as a function of the coefficients d_1, d_2, d_3 .

The numerical shooting method was employed using parameter values $\alpha = 1, \xi_1 = 1, \xi_2 = 0.5, \Lambda = -0.5$, and $Q_m = 2$. In this case, the irrelevant modes at the horizon scaled with exponents $\nu = 1$ (where we have chosen $d_1 = -0.001$ and $d_2 = 0.0015$) and

Figure 1. Metric functions in the intermediate Lifshitz regime. The numerical solution is plotted in blue while the behavior of an exact Lifshitz solution (with $\alpha = 1$) is shown in red. On the left is $a'(r)$, and on the right is $b(r)$.

Figure 2. Here we see a log-log plot of the crossover from Lifshitz scaling to AdS_4 in the metric functions $a(r)$ and $b(r)$. The crossover occurs around $r = 10^{11}$. For $r < 10^{11}$, the Lifshitz region persists over several decades in r , while for $r > 10^{11}$, the solution becomes AdS_4 . Left: $a'(r)$; right: $b(r)$. The flow in $a(r)$ just reflects the fact that the coefficient of the linear term in $a(r) \sim r$ is different in the Lifshitz and AdS_4 regions. The change in slope in the log-log plot for $b(r)$ indicates the difference between a solution with dynamical scaling ($z = 5$, for our choice of parameters) and the $z = 1$ characteristic of AdS_4 .

$\nu \approx 0.4$ (where we have chosen $d_3 \approx -0.17$). The values of the coefficients of the irrelevant perturbations to the $AdS_2 \times R^2$ solution were chosen in order to achieve a Lifshitz scaling region which persisted over several decades in r .

In figure 1 we show the solution for the metric functions $a'(r)$ and $b(r)$ in the intermediate Lifshitz regime, as well as the exact Lifshitz solution of the uncorrected action given our parameter values α and Q_m . We see that the metric functions approach the Lifshitz solution around $r = 10^4$ and remain there for several decades.

After remaining in the Lifshitz scaling region for several orders of magnitude in r , the solution eventually crosses over to AdS_4 . We show this behavior in figure 2. The value of r where the crossover occurs, $r \sim 10^{11}$, is in very good agreement with our rough estimate (3.2). This indicates that our understanding of the basic physics of the flow is correct.

In figure 3 we show the behavior of the solution for the dilaton. In the Lifshitz region, the dilaton behaves as a log with slope given by $K = \frac{\alpha/2}{1+(\alpha/2)^2}$ and it eventually crosses over to AdS_4 , where it takes a constant value ϕ_∞ .

Figure 3. Left: shown in blue is the numerical solution for $\phi(r)$ in the Lifshitz scaling regime, with the exact Lifshitz solution shown in red. Right: log-log plot of $\phi(r)$ showing crossover from Lifshitz scaling to AdS_4 . As in figure 2, the crossover occurs around $r = 10^{11}$, where we see $\phi(r)$ transition from a log-running function to a constant solution ϕ_∞ .

4 Discussion

One of the common ways of obtaining dynamical scaling in holographic theories has been to study charged black brane solutions of Einstein-Maxwell-dilaton gravity. However, the resulting Lifshitz solutions have a running dilaton, and therefore the deep IR behaviour is not expected to maintain the scaling form of the metric [17]. Instead, it is expected that in the magnetic (electric) black branes, quantum corrections (α' corrections) should modify the very near-horizon geometry. We have argued here that one generic consequence, in the magnetic case, can be the re-emergence in the deep IR of an attractor fixed point with fixed dilaton and an $AdS_2 \times R^2$ geometry (as occurs also in the Einstein-Maxwell system in the absence of a dilaton). Then, the richest solutions exhibit three scaling regions: a UV AdS_4 fixed point, an intermediate region (which can extend over many decades in energy scale) with dynamical critical exponent governed by the detailed form of the dilaton coupling, and a deep IR $AdS_2 \times R^2$ geometry.

We close with some comments/questions.

- We chose to incorporate a certain set of corrections in g in (1.5), just keeping $\xi_{1,2}$. Clearly, in general one would have there an infinite series. Our approximation in truncating at the order we did could only be justified if for some reason ξ_2 were large enough to yield a weak-coupling value of ϕ_H , with further terms of higher order in g being negligible. There is no reason to expect this to happen in general. However, the important point is that once there are multiple orders in g appearing in the gauge coupling function, there will generically be critical points in the attractor potential. The Lifshitz solutions only obtain when one has a “runaway attractor” (as described in [17]), and so the fact that generic corrections yield other non-runaway critical points explains why we feel the results we’ve described here do capture one generic *possible* fate for the near-horizon geometry of the magnetic branes.

Of course, in a system with multiple attractor minima, different minima will control different basins of attraction and the so the IR geometry may depend sensitively

on the value of the dilaton at the boundary. Different attractor minima could give different geometries, not all AdS_2 -like, in a full system. It would be interesting to study richer attractor potentials in this context, to explore how often the system enjoys different fates.

- In the magnetically charged branes, g runs toward strong coupling at the horizon, which explains why higher order corrections in g can become important and change the very near horizon geometry. In the electric case, instead g flows towards weak coupling. Then, one expects that in a theory like string theory which has a UV scale $M_s = gM_P$, α' corrections will become important. It would be interesting to show that generic higher-derivative corrections (with suitable g dependence) yield a similar result for the electrically charged black-branes. This is technically slightly more involved because of the need to deal with higher derivative equations of motion, but it should be tractable. It is easy to see that higher derivative corrections with suitable g dependence do yield $AdS_2 \times R^2$ solutions to the equations of motion.
- It was clear from the beginning that because of the running dilaton, the Lifshitz-like solutions of [17, 19] should not be expected to remain valid down to arbitrarily low energy scales - one has not attained a true scale-invariant fixed point if the scalar field breaks the scaling symmetry of the metric. On the other hand, there are plenty of Lifshitz solutions (in macroscopic theories [6] and in string theory [7–13]) which have exact scale invariance and do not involve a running scalar. Then, there is no excuse for quantum corrections or α' corrections to grow large and smoothly deform the near-horizon geometry, as happened here. In these exact Lifshitz solutions, we expect the quantum or stringy fate of the horizon could be quite different. In fact, the singularities there may be a feature, mirroring the stronger IR singularities present in scale-invariant field theories with $z > 1$. Some interesting work trying to resolve this issue by studying Coulomb branch probes of such theories is underway [35].
- There has also been recent interest in more general metrics with both dynamical critical exponent z and hyperscaling violation parameter θ , which arise in very similar Einstein-Maxwell-dilaton theories with simple dilaton potentials [22, 23, 26, 36–40]. This is in part because such metrics give rise, for appropriate θ , to phases which violate the area law for (holographic) entanglement entropy [36–39]. These metrics are also supported by a running dilaton which violates the scaling, and we expect that IR modifications similar to those we saw here will also occur rather generically in that setting. In particular, corrections to the exponential scaling potential used in those systems are also rich enough to give rise, rather generally, to critical points in the attractor potential for the dilaton which support $AdS_2 \times R^2$ solutions.
- We find that our results help add to the general confusion about the correct ground state for doped holographic theories in e.g. AdS_4 . The $AdS_2 \times R^2$ geometry of the extremal Reissner-Nordstrom black brane has a notorious extensive ground-state en-

trophy, which leads us to believe it should be a rather unstable phase.⁴ One motivation for adding the dilaton and seeing its effects on the charged black brane geometry in asymptotically AdS_4 theories in [17] was precisely to resolve this problem, and indeed the Lifshitz-like emergent IR metrics do have vanishing entropy at zero temperature. However, the same dilaton which supports the modified geometry leads to a breakdown of the g or α' expansion in the deep IR, and we see here that one generic result can be a re-emergent AdS_2 ! Quite possibly, a more detailed study of the phase diagrams of these toy models would reveal that more general phases — the homogeneous anisotropic phases of [5] or even inhomogeneous phases — are the truly generic endpoints of holographic RG flows induced by doping 3d CFTs with a charge density. In fact, the analysis in section 5 of [34] indicates that such instabilities should be generic in $AdS_2 \times R^2$ solutions of more involved dilaton gravity theories that also have a non-trivial near-horizon scalar potential driving the RG flow of the dilaton. This makes it promising to look for flows from homogeneous, anisotropic phases to the finite z, θ metrics with hyperscaling violation that arise in the presence of dilaton potentials.

Because the $AdS_2 \times R^2$ geometry we found here is stabilised by quantum corrections, the entropy density is actually smaller by a factor of the coupling than it would be in a pure Einstein-Maxwell theory without running dilaton. One can see this by comparing the entropy of two solutions with fixed ϕ_∞ - one of them with finite α , and the other with $\alpha \rightarrow 0$ (which is the Einstein-Maxwell limit). The ratio of entropy densities, when the horizon is stabilized at weak coupling in the finite α theory ($\xi_2 \gg 1$) and so the discussion is reliable, is given by

$$\frac{S_\alpha}{S_{\text{Einstein-Maxwell}}} \sim \frac{g_\infty}{g_h} \quad (4.1)$$

where g_∞ is the (shared) coupling at infinity, and g_h is the coupling at the horizon in the magnetic solution of the theory with finite α . Because the flow in these solutions is towards stronger coupling, $g_h \gg g_\infty$ and the ground-state degeneracy is somewhat relaxed.

- Finally, it is an important question to study similar examples in full string theory solutions, where we know there is a bona fide dual quantum field theory whose dynamics at finite charge density is captured by the gravity solution. This may be possible by first embedding such solutions into string-derived gauged supergravities along the lines of [32], for instance.

Acknowledgments

SK would like to thank Sandip Trivedi for very helpful discussions about related subjects. We also thank Sean Hartnoll for helping us with confusions about higher-derivative theories

⁴In fact, a general argument which indicates that the fixed points dual to such geometries have an IR divergent density of states, and should therefore not survive down to arbitrarily low energies, was presented around equation (23) of [41].

in an earlier approach to this problem, and Xi Dong, Don Marolf, John McGreevy and Mike Mulligan for interesting comments. We are grateful to the KITP and the participants in the “Holographic Duality and Condensed Matter Physics” workshop for providing a supportive environment while issues related to this work were under investigation. SK also acknowledges the hospitality of the Aspen Center for Physics, and the Aspen Music Festival for providing stimulating musical accompaniment for thoughts about black branes. This work was supported in part by the US DOE under contract DE-AC02-76SF00515 and by the National Science Foundation under grant no. PHY-0756174. SH is supported by the ARCS Foundation, Inc. Stanford Graduate Fellowship.
